

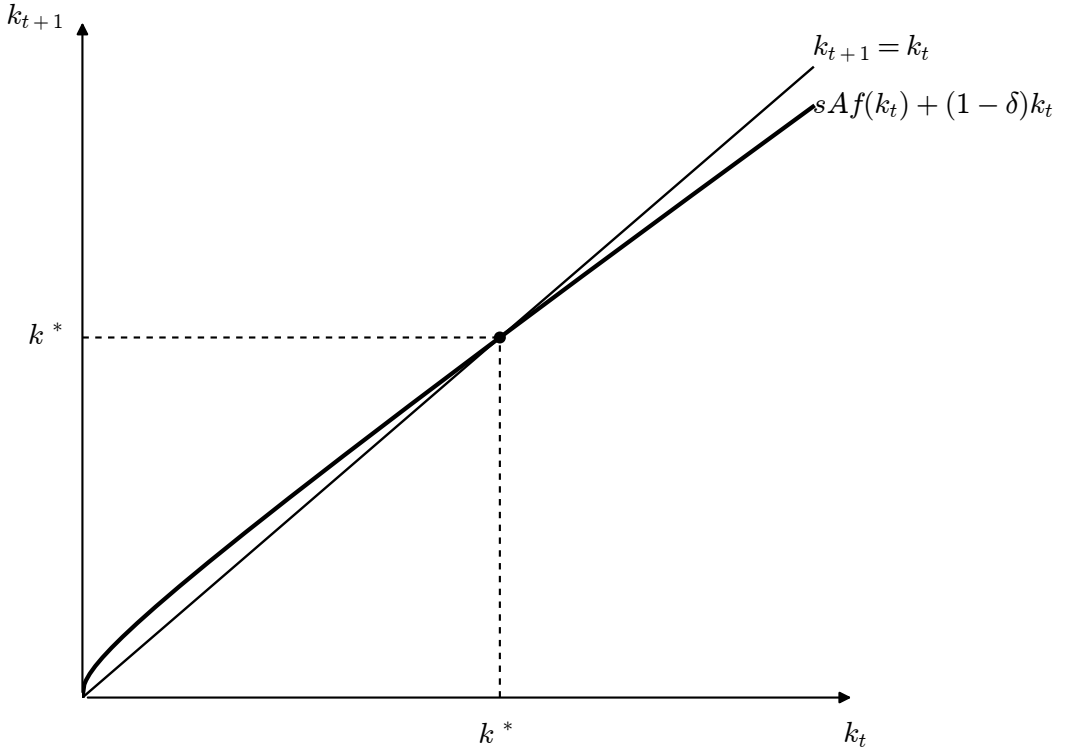

Fig. 1: The steady state, where the central equation crosses the 45° line.

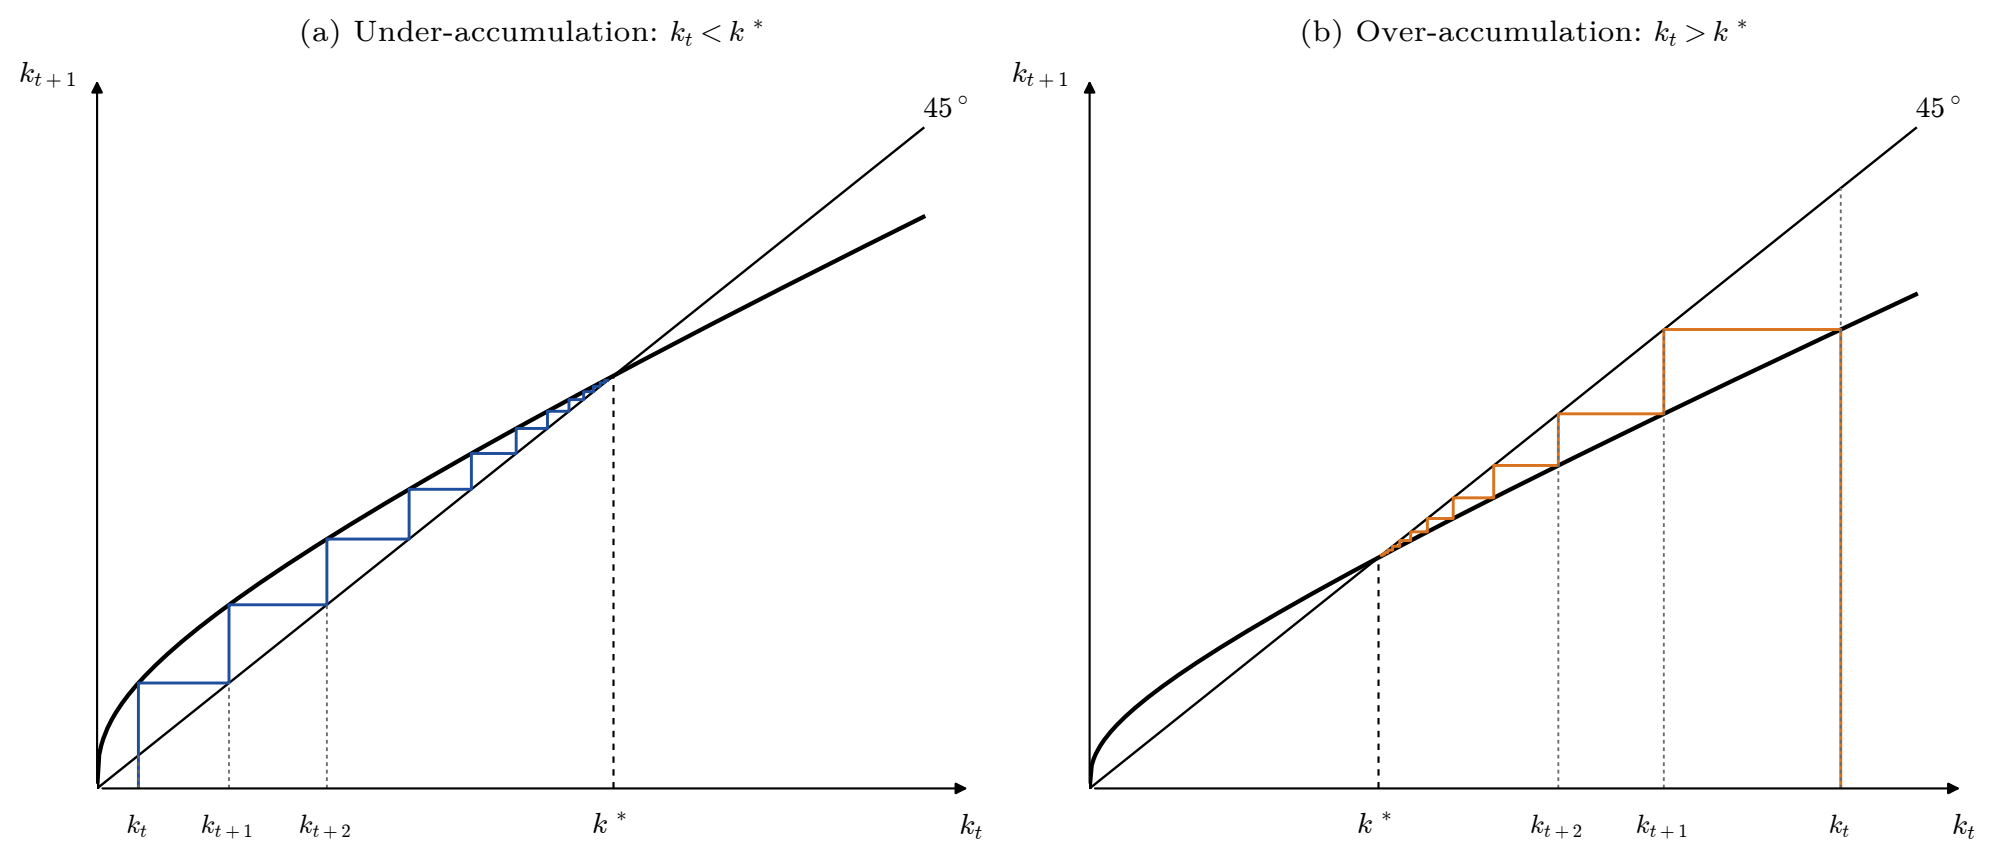

Fig. 2: Wherever it starts, capital per worker converges to k^*: the equilibrium is stable.

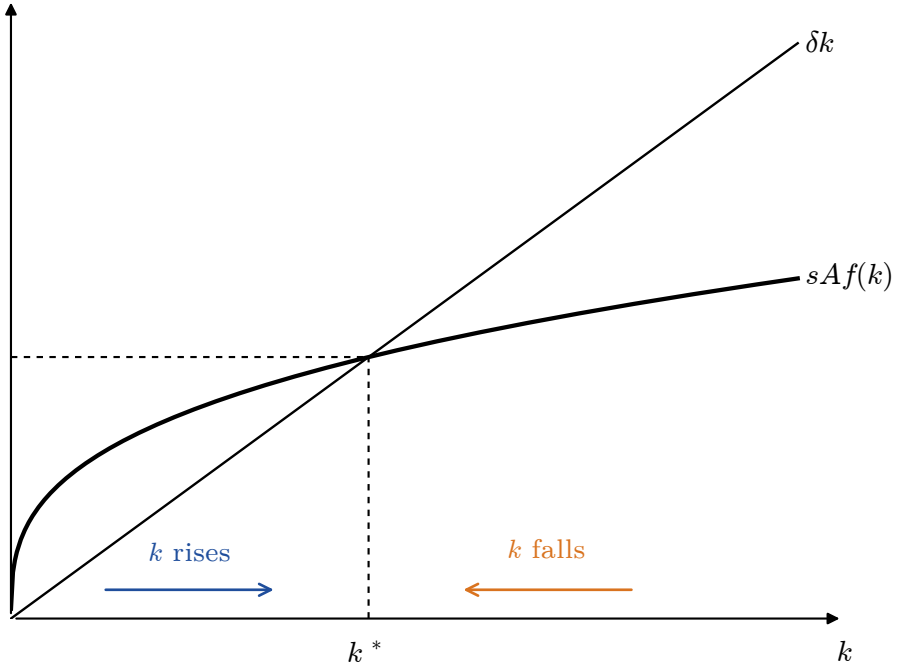

Fig. 3: In the steady state, investment per worker exactly offsets depreciation.

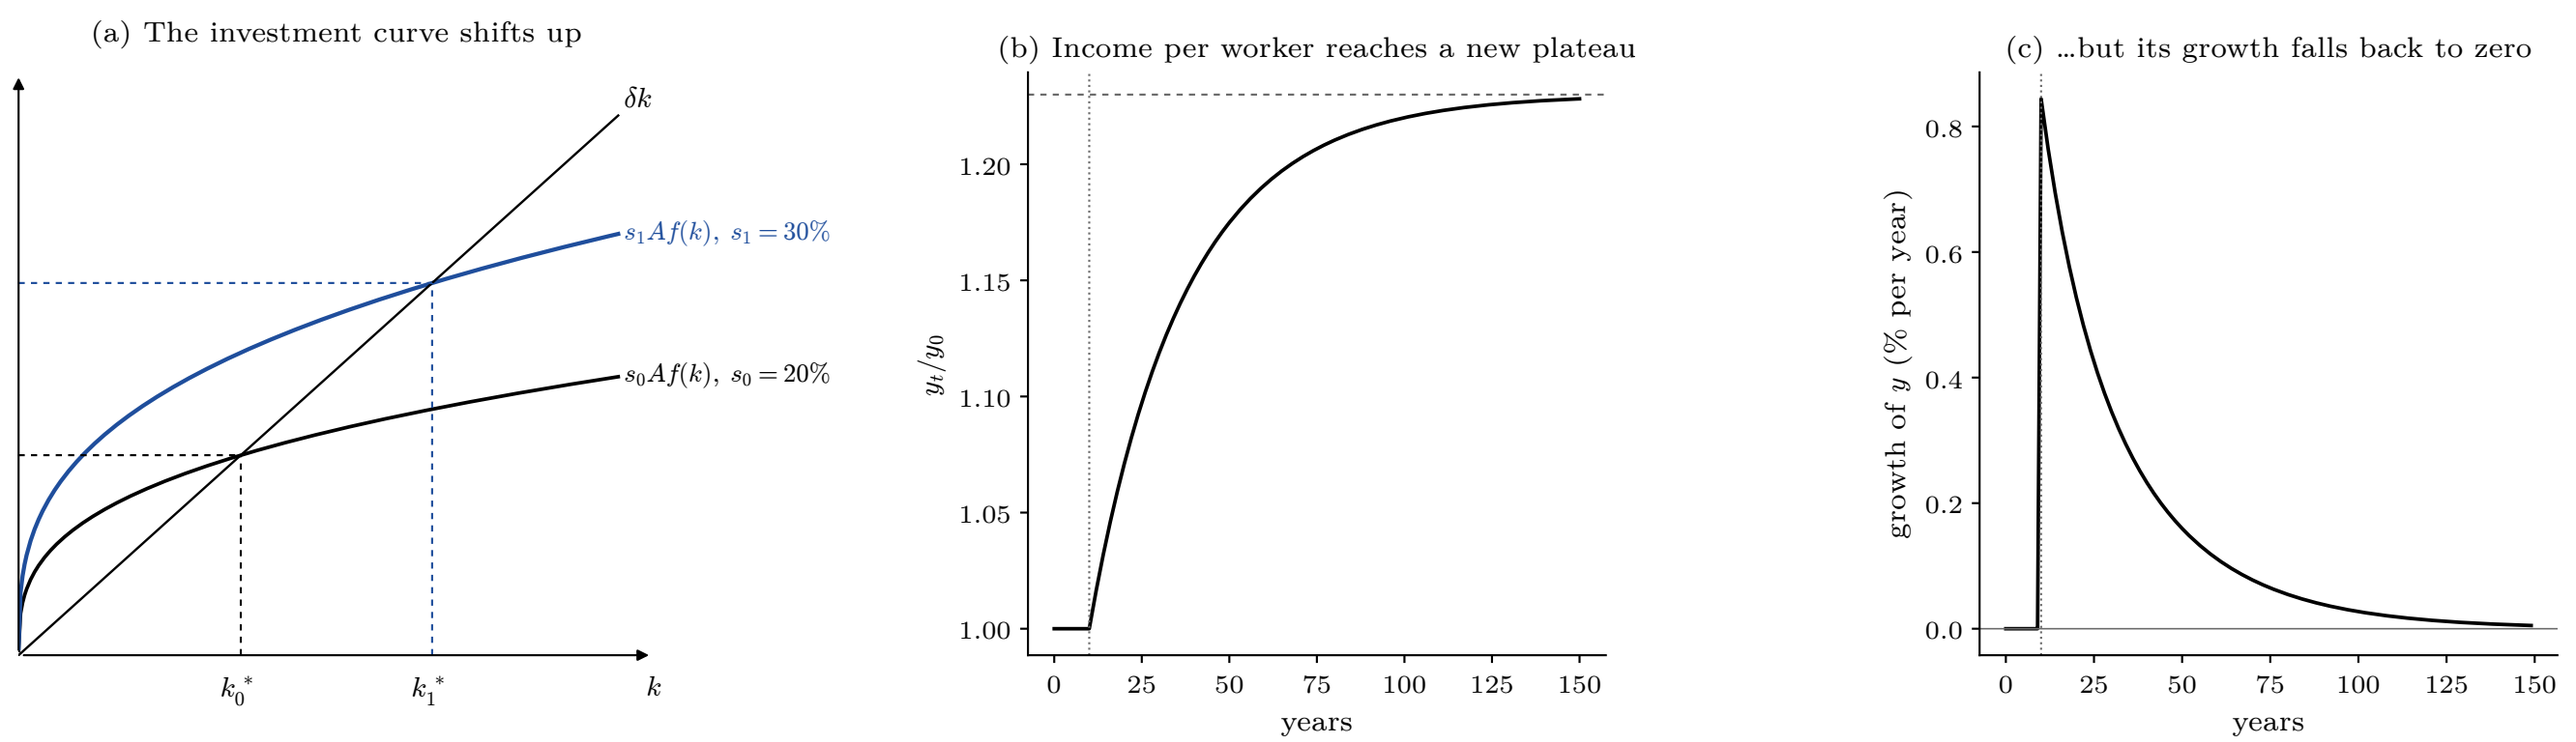

Fig. 4: Saving rate raised from 20% to 30% (Morocco's level): a level effect, not permanent growth.

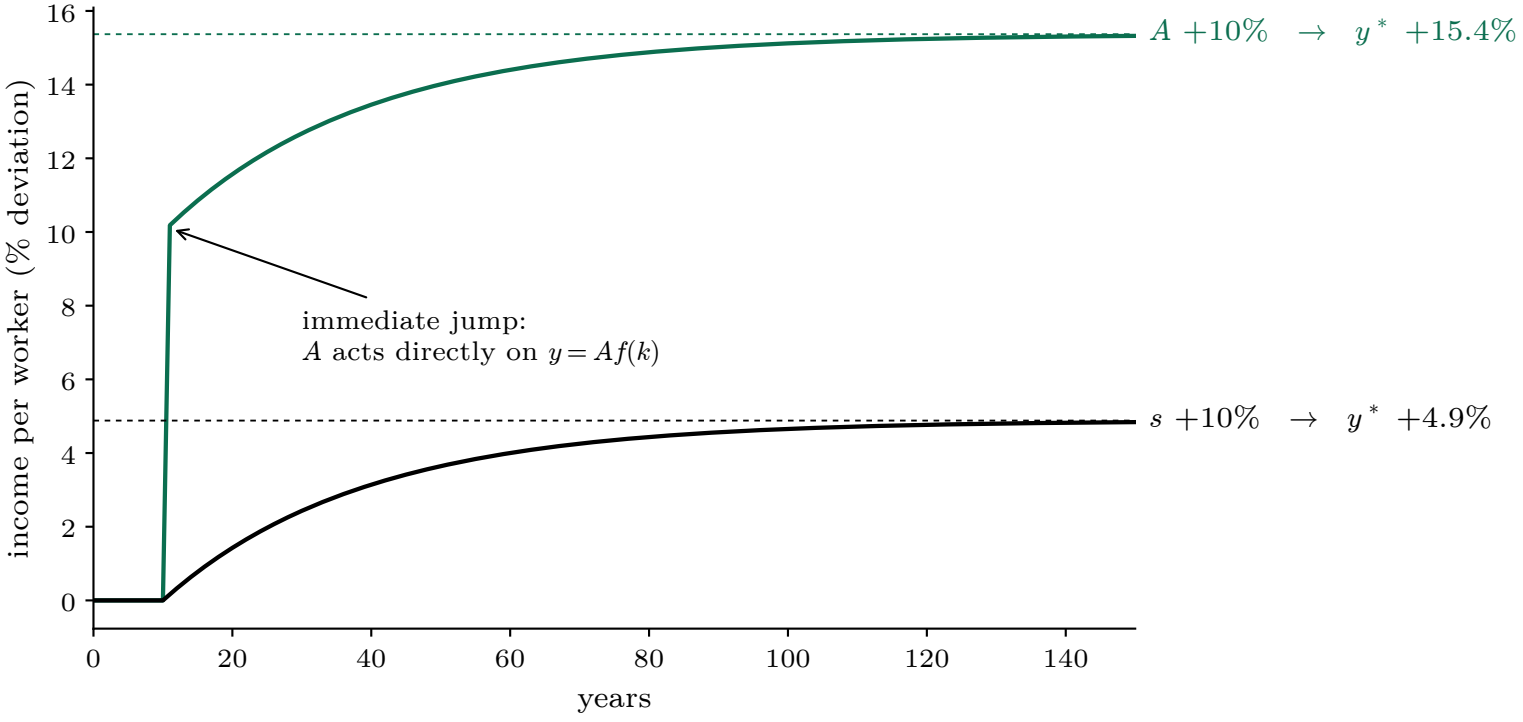

Fig. 5: The same 10% shock: productivity yields three times more than saving.

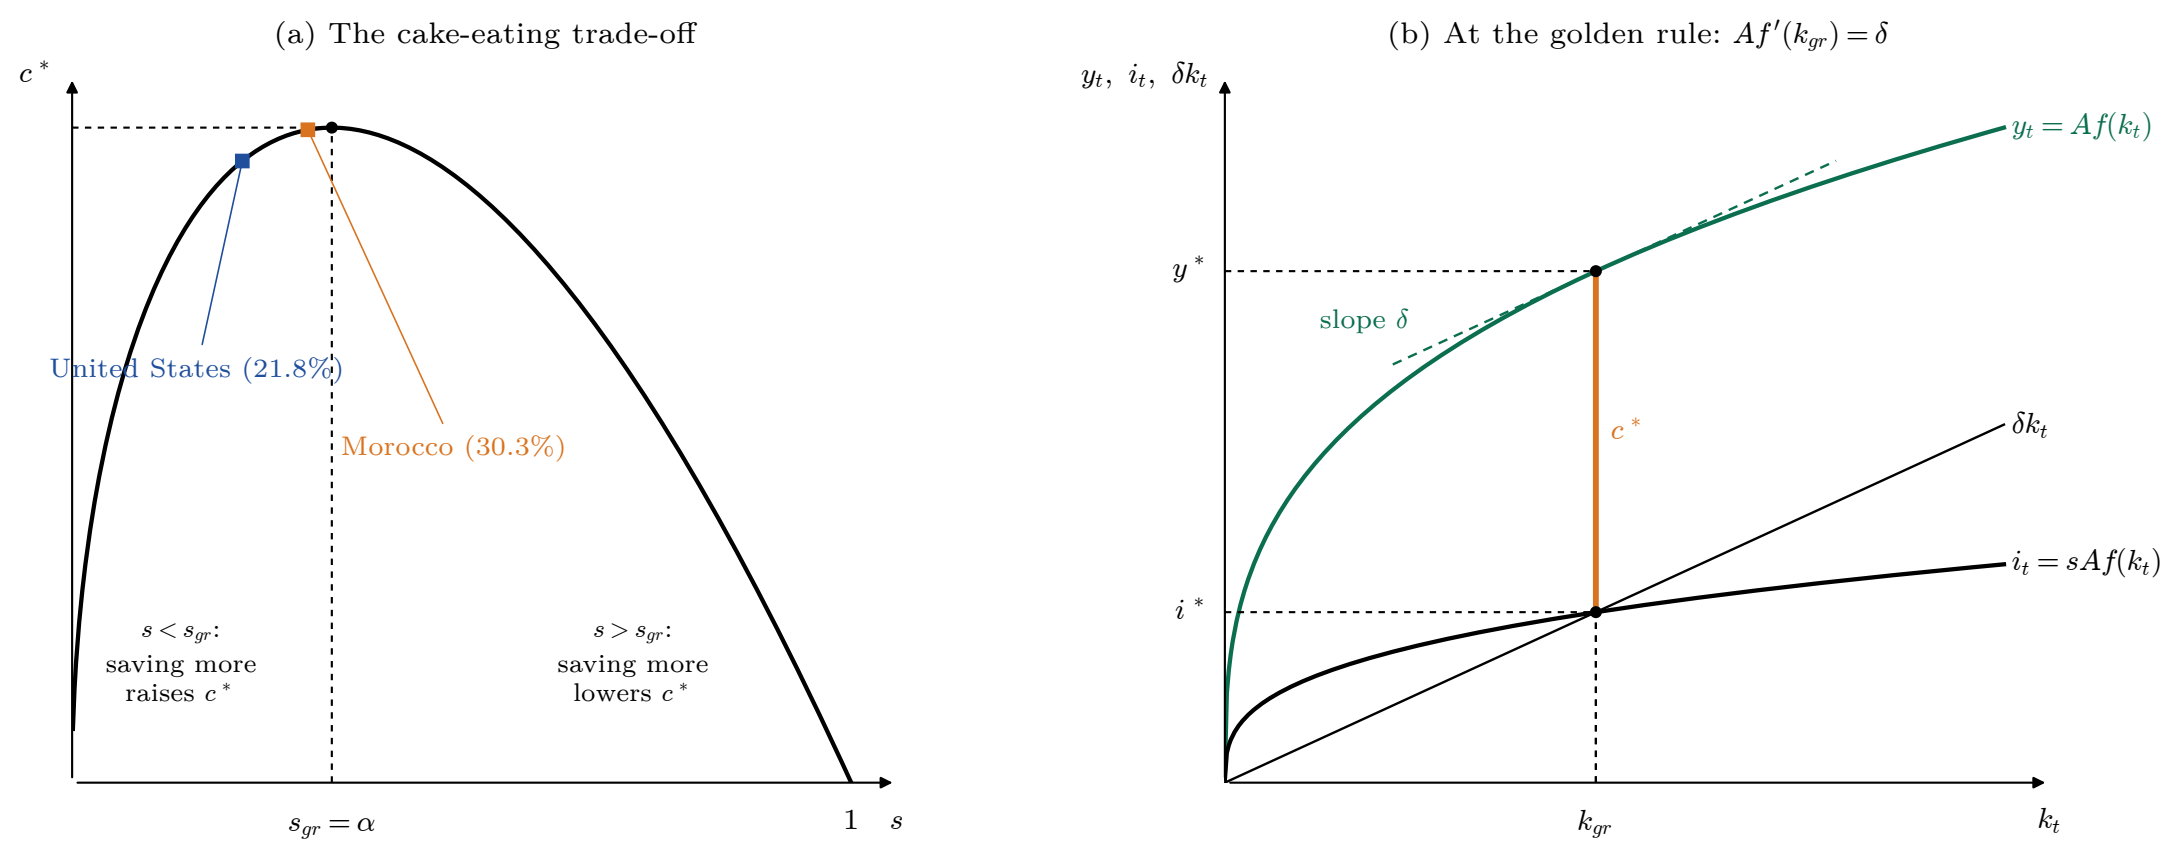

Fig. 6: The golden rule: c^* is maximized when $s = \alpha$, i.e. when the tangent to $y = Af(k)$ has slope δ.

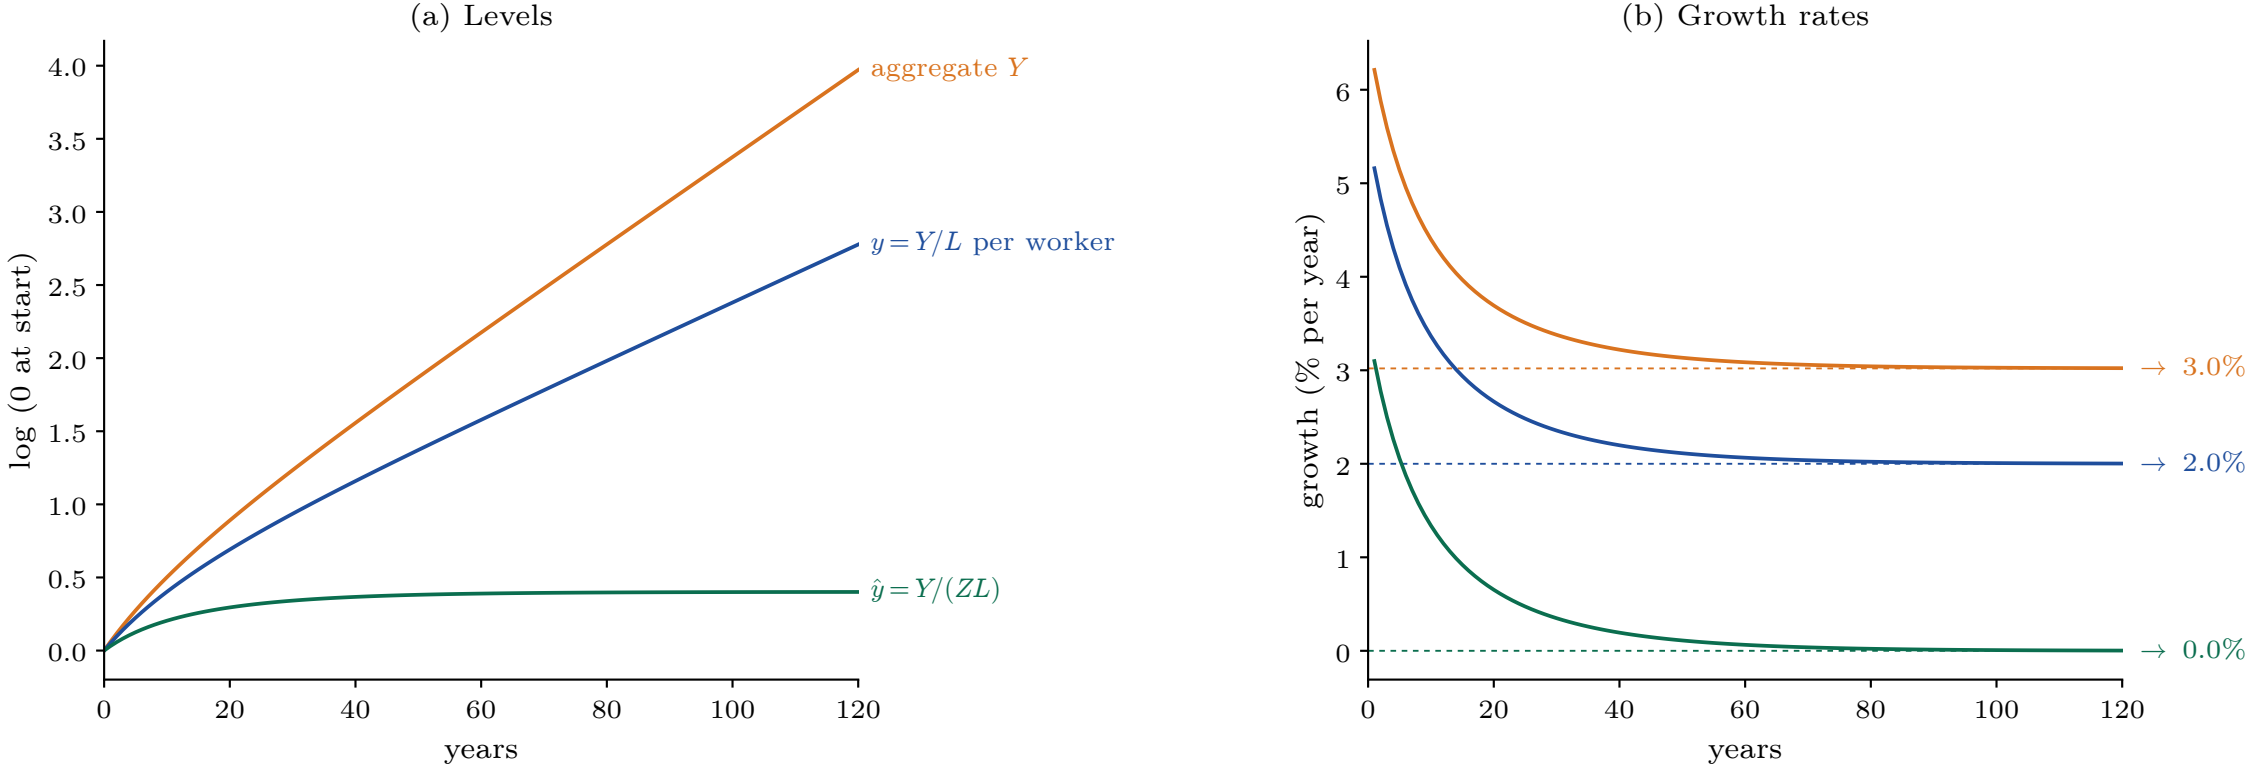

Fig. 7: Augmented Solow ($n = 1\%$, $z = 2\%$): in the long run, $\hat{y}$ is constant and y grows at the rate z of technical progress.

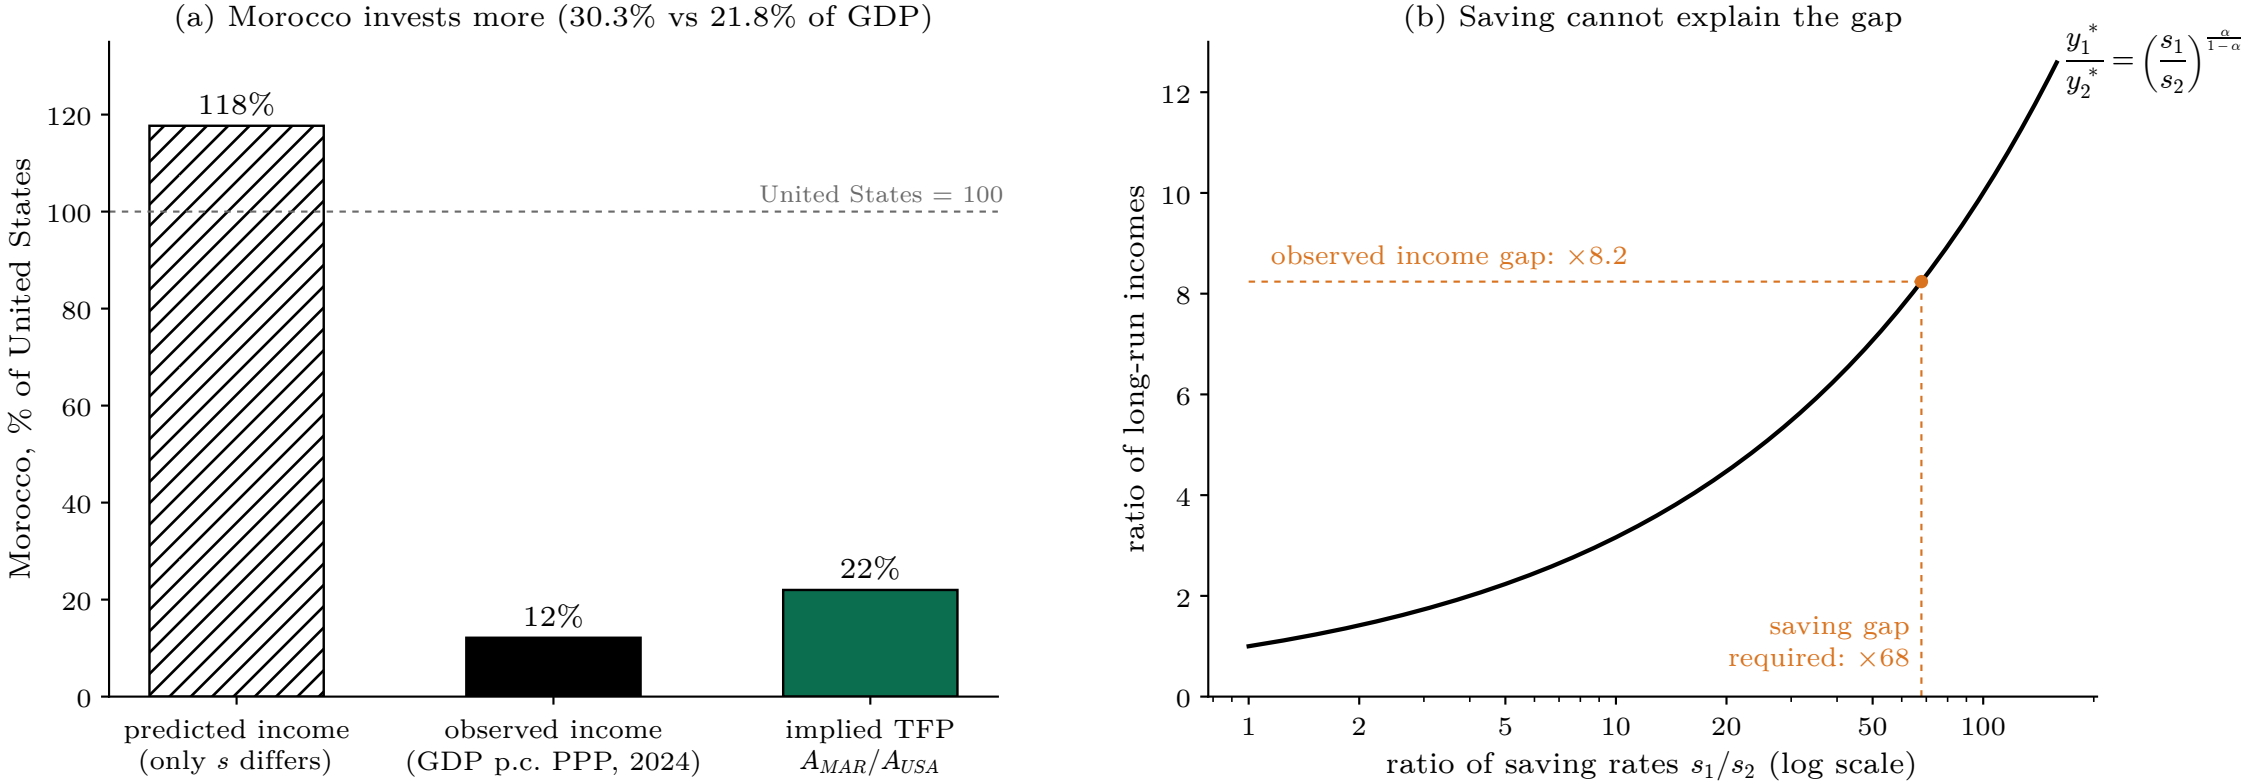

Fig. 8: Confronting Solow with the data: through the lens of the model, A accounts for most of the income gap.
